1. A researcher has developed a new drug designed to reduce blood pressure. In an experiment, 20 subjects were assigned randomly to the treatment group, and received the new experimental drug. The other 20 subjects were assigned to the control group, and received a standard, well known treatment. After a suitable period of time, the reduction in blood pressure for each subject was recorded. A summary of these data is:

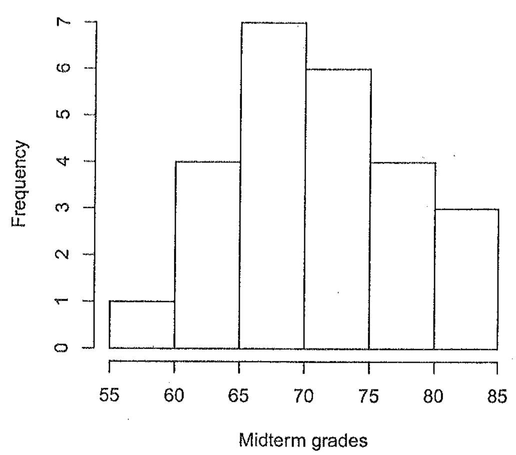
	n	$\bar{x}$	s
Treatment group (new drug):	20	23.48	8.01
Control group (old drug):	20	18.52	7.15

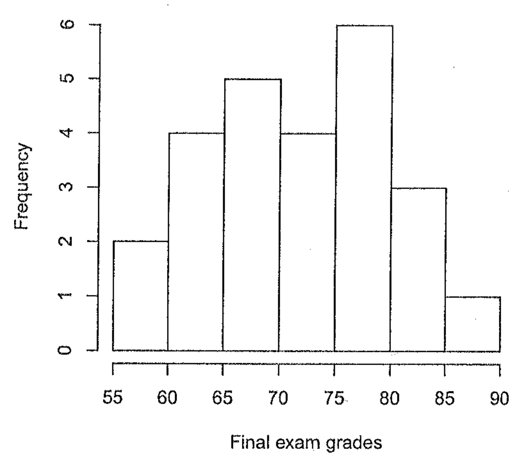
(a) (3 points) Construct a 95% confidence interval for the difference in the average reduction of blood pressure between treatment and control group.

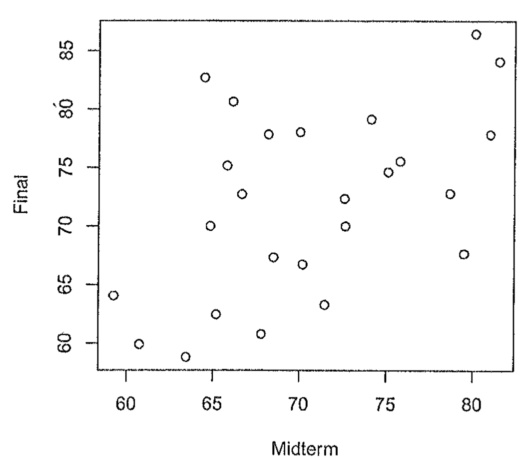
(b) (3 points) This study found that the effect of the new drug on men might be different from the effect on women. In another experiment, 20 women and 20 men volunteered. Half of the men were randomly assigned to the new drug and half of the women were randomly assigned to the new drug. The remaining volunteers received the old drug. What is this design? Is this design better than the first experiment described previously? Explain.

2. (3 points) An engineering system consists of 2 components, and these 2 components work independently. The probability that the first component fails is 1/3 and the probability that the second component fails is 1/4. If at least one component fails, the whole system stops working. What is the chance that the whole system fails?

3. Looking at the midterm grades and final exam grades of a simple random sample of 25 students from a very large class, the average grade for midterm is 70.9 with a standard deviation 6.9, and the average grade for final exam is 71.1 with a standard deviation 7.0. The correlation between the midterm grades and final exam grades is 0.5. The histograms for the midterm grades and final exam grades, and the scatterplot of midterm grades and final exam grades are shown below.







(a) (4 points) If a student's midterm grade is in the top 2.5% of all students who took this class, what would you predict is his final exam grade? Be clear about any assumption you must make to do the problem.

(b) (2 points) Why should we not have been surprised to see that the students who have done well on midterm exam did worse on the final exam?

(c) (2 points) Construct a 95% confidence interval for the average midterm exam grade of the whole class.

4. (5 points) In the United States, there is a strong relationship between smoking and education, with well-educated people less likely to smoke. A study in France included a sample of 459 men who were selected at random from men who had visited a health center for a routine checkup. Education is classified into three categories corresponding to the highest level of education and smoking status is classified into four categories.

	Smoking status				
Education	Nonsmoker	Former	Moderate	Heavy	total
Primary school	56	54	41	36	187
Secondary school	37	43	27	32	139
University	53	28	36	16	133
Total	146	125	104	84	459

Carry out a χ^2 test at significance level 0.05 to see if there is a relationship between smoking and education in France. As part of your answer you should complete the following tables:

Expected Cell Counts

	Smoking status			
Education	Nonsmoker	Former	Moderate	Heavy
Primary school	59.481		42.370	34.222
Secondary school	44.214	37.854		25.438
University	42.305	36.220	30.135	

Components of χ^2

	Smoking status			
Education	Nonsmoker	Former	Moderate	Heavy
Primary school	0.204		0.044	0.092
Secondary school	1.177	0.700	0.642	
University		1.865	1.141	2.858

5. (7 points) An SRS of 100 flights of a large airline (airline 1) showed that 64 were on time. An SRS of 100 flights of another large airline (airline 2) showed that 80 were on time. Is there evidence of a difference in the on-time rate for the two airlines, at the significance level 0.05?

6. Do SAT coaching classes work? Do they help students to improve their test scores? Nine students were selected randomly from all of the students that completed an SAT coaching class. For each student, we recorded their first SAT score (before the class) and their second SAT score (after the coaching class).

Student	1	2	3	4	5	6	7	8	9	Mean	SD
First SAT score	875	834	902	935	857	879	874	940	899	888.3	34.6
Second SAT score	840	871	906	960	940	843	964	962	952	915.3	51.8
Second - First	-35	37	4	25	83	-36	90	22	53	27	45.1

(a) (6 points) Does the data suggest that the average after-class SAT score is higher than the average before-class SAT score, at the significance level 0.05? Be clear about any assumption you must make to do the problem.

(b) (2 points) Will it be correct to use a two-sample t test on this data? Explain.

7. As a homework exercise each student in a class selected two separate simple random samples from two different populations.

   (a) (6 points) Each students used the sample to construct a 90% Z confidence interval for the population mean for each population. There are 200 students in the class. If the students work independently, what is the chance that less than 170 get the two confidence intervals both cover the true value of the two population means.

(b) (2 points) One of the 90% confidence intervals for the first population mean is (95.1, 104.9). Can we interpret it as "the probability that this interval (95.1, 104.9) covers the true value of the first population mean is 95%"? Why?

(c) (2 points) If we expect the probability that the two confidence intervals both cover the true values of the two population means to be 95%, what confidence level would each confidence interval is expected to have?

8. (5 points) A plan for an executive travellers' club has been developed by an airline on the premise that at most 5% of its current customers would qualify for membership. A random sample 500 customers yielded 40 who would qualify. Using this data, test at the significance level 0.01 the null hypothesis that the company's premise is correct against the alternative that its is not correct.

9. There are $n = 100$ observations from a Normal population with known population standard deviation $\sigma = 5$ with unknown population mean μ. We will test $H_0 : \mu = 0$ and $H_a : \mu > 0$ with fixed significance level $\alpha = 0.025$. Find the test power, the probability of rejecting H_0 when $\mu = 0.5$, by the following these steps.

   (a) (2 points) The z test statistic is

$$z = \frac{\bar{x} - \mu_0}{\sigma/\sqrt{n}} = \frac{\bar{x} - 0}{5/\sqrt{100}} = 2\bar{x}.$$

   What values of z lead to rejecting H_0 at the 2.5% significance level? [Hint: This question is asking what values of z lead to the P-values smaller than 0.025. The z test statistic has a standard Normal distribution when H_0 is true. Since the alternative hypothesis is one-sided, the P-value is the area to the right of z value under the standard Normal curve.]

   (b) (1 point) Based on your result in (a), what values of $\bar{x}$ lead to rejecting H_0?

   (c) (2 points) What is the sampling distribution of $\bar{x}$ when $\mu = 0.5$?

   (d) (3 points) The power is the probability that you reject H_0 when $\mu = 0.5$. What is the probability?

BMTables.indd Page 676 11/15/11 4:25:16 PM user-s163 user-F452 EQA

Table entry for z is the area under the standard Normal curve to the left of z.

Table entry for C is the critical value t^* required for confidence level C. To approximate one- and two-sided P-values, compare the value of the t statistic with the critical values of t^* that match the P-values given at the bottom of the table.

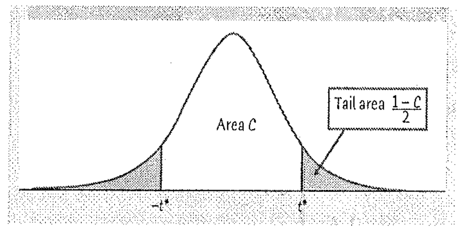

TABLE C t distribution critical values

DEGREES OF FREEDOM	CONFIDENCE LEVEL C											
	50%	60%	70%	80%	90%	95%	96%	98%	99%	99.5%	99.8%	99.9%
